KEYWORDS
Mathematical simulation, synchronous machine, magnetic field.

ABSTRACT
This paper describes a methodology for determining the interdependencies between individual characteristics of synchronous machines using numerical experiments and for replacing the interdependencies with the analytical expression in a polynomial format. This approach facilitates further investigations, since it allows to replace real experiments. The proposed methodology is easy to implement with computer technologies. The method is based on the mathematical modelling of magnetic field using partial differential equations of derivatives in relation to the magnetic vector potential, realized by the method of finite element. This method, which is described here and proven theoretically, offers how to obtain the vectorial magnetic potential as a spatial coordinate and a time function $A(x,y,t)$ as well as to determine its characteristics by mathematical modelling of stationary magnetic field. Offered, in theory proved, and described method proposes how from a stationary magnetic field’s mathematical modelling the vector magnetic potential as a spatial coordinates and as a time function, necessary characteristics are obtained.

INTRODUCTION
A certain group of the various synchronous machine’s characteristics represents the connections between the armature voltage $U$, armature current $I$, excitation current $I'$ and power factor $\cos \phi$. These values in stationary condition define important values for operation as consumed (engine mode) or produced (generator mode) active and reactive power, as well as the electromagnetic moment. The characteristic can be obtained experimentally, but this is impossible at the design stage, particularly while developing a new non-traditional design when prototype production appears labour-demanding and expensive. In present circumstances, the most promising method is mathematical modelling of the electromagnetic field with quantitative methods. Computer-based mathematical modelling techniques allow calculation of the model of the real machine with high precision. It is possible to reproduce precisely the geometrical configuration of individual elements of magnetic system as well as to reproduce the non-linear influence consideration characteristics of magnetic materials. The magnetic field’s mathematical modelling is based on the finite element method, implemented by using the multi-purpose software package QuickField. Mathematical modelling is based on the stationary field equation considering the vector magnetic potential, which, assuming that the machine’s field is plane-parallel, has only one component A (Bianchi 2005):

$$\frac{\partial^2 A}{\partial x^2} + \frac{\partial^2 A}{\partial y^2} = -\mu j_0,$$  \hspace{1cm} (1)

where $\mu$ – magnetic permeability, $j_0$ – current density of field sources in armature winding slots and excitation winding (Fig.1.).

![Fig. 1. The synchronous machine model (2p = 2).](image)

While simulating the synchronous machine’s magnetic field under load (the armature current $I_a \neq 0$ and excitation current $I' \neq 0$), equation (1) needs to be solved $n$ times, at fixed time moments $t_1, t_2, \ldots, t_k, \ldots, t_n$, each time at the right side of the equation, an
instantaneous current density values \( j_a(t_1) = j_{an} \sin \omega t_1, \quad j_a(t_2) = j_{an} \sin \omega t_2, \ldots \). After solving this equation it is possible to obtain task vector potentials values. These values can be displayed in the table form as a functional connection of spatial coordinates \( x \) and \( y \) in fixed time moments \( t \). In addition, it is necessary to take into account the rotor position change in relation to the armature field axis, which rotates with synchronous speed.

Determination of synchronous machine parameters and the characteristics often requires determination of resultant magnetic flux in the air gap or the one pole flux \( \Phi_\delta \), which flows into the stator. The following formula is used to determine the magnetic flux: \( \Phi_\delta = (A_j - A_i)l \), where \( A_j \) and \( A_i \) are the magnetic vector potential values on the stator surface at points 1 and 2 (Fig.1), \( l \) – the length of the machine in axial direction.

In this case, due to rotor’s symmetry \( A_1 = -A_2 \), where \( A_1 \) and \( A_2 \) are the magnetic vector potential values at points 1 and 2. Considering that, magnetic flux in the air gap can be calculated as

\[
\Phi_\delta = 2A_1l. \tag{2}
\]

**PROCESSING METHODS OF MODELLING RESULTS AND DETERMINATION OF CHARACTERISTICS**

By examining the magnetic vector potential distribution on the stator surface and by implementing the harmonic analysis, the first and the higher harmonics amplitude and phase values are obtained. After that the first harmonic e.m.f. calculation is possible using the formula (Mesnajevs and Zviedris 2010)

\[
E_{\delta 1} = 4.44f_1k_w \frac{2p_1q_1w_{wp}}{a_1} 2A_{im}l, \tag{3}
\]

where \( A_{im} \) - the first harmonic amplitude value of the vector magnetic potential; \( f_1 \) - network frequency; \( k_w \) - winding factor; \( \frac{2p_1q_1w_{wp}}{a_1} \) - number of turns of one phase of the armature winding.

One of the research tasks is to determine the excitation winding’s current \( I_f \) (or magnetization force \( F_f \) of excitation winding), which provides the given voltage \( U \), the armature current \( I_a \) and the power factor \( \cos \phi \).

Synchronous machine armature and excitation windings are spatially differently positioned and, therefore, the winding magnetization forces produce different flux sizes in the air gap. To be able to use the above mentioned value, it is necessary to reduce armature magnetization currents or magnetization force to the excitation winding, taking into account differences of the armature field and the excitation field by the form factor (Voldek 1974).

**Fig.2. The vector diagram of synchronous machine.**

There is a complex and non-linear connection Between \( E_\delta \) and \( F_\delta \). It may be expressed only in a numerical form. When the finite element method is applied, magnetic field calculations \( F_f \) (or \( E_\delta \) can only be determined by iterative procedures. To rationalize the process \( 3 \) \( \varepsilon \) values (e.g. \( \varepsilon_1 = \varepsilon_{min} \), \( \varepsilon_3 = \varepsilon_{max} \), \( \varepsilon_2 = (\varepsilon_{min} + \varepsilon_{max})/2 \), \( \varepsilon_{min} \) and \( \varepsilon_{max} \) values can be selected from the synchronous machine vector diagram in the unsaturated condition (Mesnajevs and Zviedris 2010)) and the excitation 3 current \( I_f \) values (e.g. \( I_{f1} = I_{fmin} \), \( I_{f2} = I_{fmax} \), \( I_{f2} = (I_{fmax} + I_{fmin})/2 \), \( I_{fmin} \) and \( I_{fmax} \) values can be selected within the range 0,5 \( I_f \leq 2,5I_{fN} \), there are obtained \( 3 \times 3 = 9 \) \( \varepsilon \) and \( I_f \) combinations, which must be calculated from magnetic field. These boundaries are not defined and, if necessary, can be changed.

After the calculations of magnetic fields were made (for example using finite element method) it is necessary to determine \( U \) and \( \varphi \) values which are given in table 1 for each combination.

**Table 1 \( U \) and \( \varphi \) combination table**

<table>

</tbody>
</table>
The table above describes the two-argument functions: $U_{i,k} = f_i(I_{i},\varepsilon_k)$ and $\varphi_{i,k} = f_2(I_{i},\varepsilon_k)$. Where using these functional connections, it is necessary to find $\varepsilon$ and $I_f$ values, which provide pre-set $U$ and $\varphi$ values (for example: $U = U_N$ and $\varphi = 0$). If this function is set as an analytical expression, the task reduces to the non-linear equation system solution in relation to the $\varepsilon$ and $I_f$ sizes (Zvidrius 1999). For the approximation of the two-argument function the following polynomials can be used:

\[ U = a_1 + a_2\varepsilon + a_3 I_f + a_4 \varepsilon I_f + a_5 \varepsilon^2 + a_6 I_f^2 + \ldots \]
\[ ... + a_7 \varepsilon^2 I_f^2 + a_8 \varepsilon I_f^2 + a_9 \varepsilon^2 I_f^2, \]

\[ \varphi = b_1 + b_2 \varepsilon + b_3 I_f + b_4 \varepsilon I_f + b_5 \varepsilon^2 + b_6 I_f^2 + \ldots \]
\[ ... + b_7 \varepsilon^2 I_f^2 + b_8 \varepsilon I_f^2 + b_9 \varepsilon^2 I_f^2, \]  

where the coefficients $a_1, a_2, \ldots, a_9, b_1, b_2, \ldots, b_9$ determined by solving 9 polynomial equation systems inserting the appropriate $U_{i,k}, \varphi_{i,k}, I_f$ and $\varepsilon_k$ value.

For determination of these coefficients, the equation system can be solved in the matrix form:

\[ ZA = U \]  

(6)

and

\[ ZB = \varphi, \]  

(7)

where $Z$ is a square matrix:

\[
Z = \begin{bmatrix}
1 & e_{11} & e_{12} & e_{13} & e_{14} & e_{15} & e_{16} & e_{17} & e_{18} & e_{19} \\
1 & e_{21} & e_{22} & e_{23} & e_{24} & e_{25} & e_{26} & e_{27} & e_{28} & e_{29} \\
1 & e_{31} & e_{32} & e_{33} & e_{34} & e_{35} & e_{36} & e_{37} & e_{38} & e_{39} \\
1 & e_{41} & e_{42} & e_{43} & e_{44} & e_{45} & e_{46} & e_{47} & e_{48} & e_{49} \\
1 & e_{51} & e_{52} & e_{53} & e_{54} & e_{55} & e_{56} & e_{57} & e_{58} & e_{59} \\
1 & e_{61} & e_{62} & e_{63} & e_{64} & e_{65} & e_{66} & e_{67} & e_{68} & e_{69} \\
1 & e_{71} & e_{72} & e_{73} & e_{74} & e_{75} & e_{76} & e_{77} & e_{78} & e_{79} \\
1 & e_{81} & e_{82} & e_{83} & e_{84} & e_{85} & e_{86} & e_{87} & e_{88} & e_{89} \\
1 & e_{91} & e_{92} & e_{93} & e_{94} & e_{95} & e_{96} & e_{97} & e_{98} & e_{99}
\end{bmatrix}
\]  

(8)

but matrixes $A$, $B$, $U$, $\varphi$ are the column matrixes

\[
A = \begin{bmatrix}
a_1 \\
a_2 \\
a_3 \\
a_4 \\
a_5 \\
a_6 \\
a_7 \\
a_8 \\
a_9
\end{bmatrix}, \quad B = \begin{bmatrix}
b_1 \\
b_2 \\
b_3 \\
b_4 \\
b_5 \\
b_6 \\
b_7 \\
b_8 \\
b_9
\end{bmatrix},
\]  

(9)

\[ U = \begin{bmatrix}
U_{11} \\
U_{12} \\
U_{13} \\
U_{21} \\
U_{22} \\
U_{23} \\
U_{31} \\
U_{32} \\
U_{33}
\end{bmatrix}, \quad \varphi = \begin{bmatrix}
\varphi_{11} \\
\varphi_{12} \\
\varphi_{13} \\
\varphi_{21} \\
\varphi_{22} \\
\varphi_{23} \\
\varphi_{31} \\
\varphi_{32} \\
\varphi_{33}
\end{bmatrix}
\]  

(10)

When the coefficients $a_i$ and $b_i$ are found, they are to be placed in each of the second power degree polynomial right side, but on the left a pre-set $U$ and $\varphi$ values. Thus non-linear equations system is acquired, which must be solved with regard $\varepsilon$ and $I_f$. In order to solve these systems the two-argument function minimization with an interval exclusion method can be used.

In the interval exclusion method, there is used the unimodal characteristic of function. This feature, comprising the function $f(x)$ values at two different points in the search range allows determining in which of these sub-intervals a function’s minimum does not exist. Interval exclusion method’s positive feature is that this method requires only the calculation of function value. It is not important if this function can be differentiated, as well as it is allowed that the function is not defined in analytical form. The only requirement is that it must be possible to calculate values of function $f(x)$ in chosen searching points.

The unimodal characteristic of the effectiveness function also can be used for two-argument functions. Variables $\varepsilon$ and $I_f$ of the two-argument function while there are changes in the area $\varepsilon_{\min} < \varepsilon < \varepsilon_{\max}$ and $I_{\min} < I_f < I_{\max}$, are unimodal, if this function in the given area has only one minimum, which corresponds to the argument value $\varepsilon^*$ and $I_f^*$, or in this area the correlation (13) is correct for any $\varepsilon$ and $I_f$ values.

\[ f(\varepsilon^*, I_f^*) < f(\varepsilon, I_f) \]  

(13)

Fig. 3 presents the flowchart of the proposed two-argument function minimization algorithm.
Fig. 3. two-argument function minimization algorithm’s flowchart using interval excluding method.

Input data
$x_{\min}, x_{\max}, y_{\min}, y_{\max}, dx, dy$

$x_m = (x_{\min} + x_{\max})/2$
$y_m = (y_{\min} + y_{\max})/2$

$L_x = x_{\max} - x_{\min}$
$L_y = y_{\max} - y_{\min}$

$L_x \leq dx$
$L_y \leq dy$

yes
$x_{\text{opt}} = x_m$
$y_{\text{opt}} = y_m$

no

$x_1 = x_{\min} + L_x/4$
$x_2 = x_{\max} - L_x/4$

$f(x_1, y_m), f(x_2, y_m), f(x_m, y_m)$ calculation

$y_1 = y_{\min} + L_y/4$
$y_2 = y_{\max} - L_y/4$

$f(x_1, y_m) < f(x_m, y_m)$

yes
$x_{\max} = x_m$
$x_m = x_1$

no
$f(x_2, y_m) < f(x_m, y_m)$

yes
$x_{\min} = x_m$
$x_m = x_2$

no

$f(x_m, y_1), f(x_m, y_2), f(x_m, y_m)$ calculation

$y_{\max} = y_m$
$y_m = y_1$

no
$f(x_m, y_2) < f(x_m, y_m)$

yes
$y_{\min} = y_m$
$y_m = y_2$

no
$f(x_m, y_1) < f(x_m, y_m)$

$y_{\min} = y_1$
$y_1 = y_2$

no
$y_{\min} = y_1$
$y_1 = y_2$

no
$y_{\max} = y_2$

no
$y_{\max} = y_2$
The method described has been implemented by FORTRAN software. After the execution of the program it produces ε and $I_f$ values which provide the pre-set $U$ and $\varphi$ values. For verification, it is desirable to make backwards calculation to make sure that the program is working correctly and the calculated coefficients provide sufficient approximation accuracy.

**EXAMPLE OF CALCULATION**

3 $\varepsilon$ values ($\varepsilon_1 = 100^\circ$, $\varepsilon_2 = 120^\circ$, $\varepsilon_3 = 140^\circ$), and 3 excitation current $I_f$ values ($I_{f1} = 4A$, $I_{f2} = 7A$, $I_{f3} = 10A$) were chosen. The armature current $I_a = 6.56A$, the voltage $U = 100V$ and the power factor $\cos\varphi = 1$ (or $\varphi = 0^\circ$) were set. The results of the magnetic field calculation are summarized in the Table 2.

**REFERENCES**

**CONCLUSIONS**

As it can be seen from the table 4, the method provides sufficiently high precision. The method is applicable for synchronous machines’ (including the atypical structure) calculations. Using mathematic modelling of the magnetic field and the developed method allow determining of characteristics of synchronous machines taking into consideration individual elements geometric shapes and saturation of magnetic system.

**AUTHOR BIOGRAPHIES**

ALEKSANDRS MESNAJEVS was born in 1985 in Latvia. In 2008 he graduated Riga Technical University, obtaining the M.Sc.ing. degree. Presently he is a PhD student.

In March 2008, he acquired the certificate “Basic and advanced simulation using QuickField software”. Starting from 2006, he is working as laboratory assistant and scientific assistant at the Department of Electrical Machines and Apparatus of Riga Technical University.

ANDREJS ZVIEDRIS was born in 1938 in Latvia. In 1961, he graduated Riga Polytechnical Institute (RPI), the Faculty of Electrical and Power Engineering, obtaining the qualifications of Engineer in the Electrical Machines and Apparatus
speciality. In 1970, he defended thesis and obtained a Candidate degree of Technical Sciences. The Dr.Sc.ing. degree was conferred to A. Zviedris in 1992. After graduating the RPI, A. Zviedris has worked as an Assistant Professor (1968-1973), and Head of the Department of Electrical Machines and Apparatus (1973-1984). In 2001 he was elected as Associate Professor in the Department of Electrical Machines and Apparatus, where he works up to date. Scientific activities of A. Zviedris are related to Mathematical Simulation of magnetic fields in Electrical Machines. The results of his research are approbated in more than 50 scientific publications and technical reports in International Scientific conferences. A. Zviedris is an Expert in Standardization Technical Committee of Electrotechnical Terminology of Electrical Engineering, a member of Latvian Union of Scientists.

ANDREJ PODGORNOV was born 1980 in Latvia. In 2009 he graduated from Riga Technical University, gaining Ph.D. degree. From 2004 he is working as a laboratory assistant and since 2008 as lecturer in Electrical Machines and Apparatus Department of Riga Technical University. In 2010 he was elected as Assistant Professor at the Department of Electrical Machines and Apparatus, where work to date. Scientific activities of A. Podgornov are related to Mathematical Simulation of magnetic fields in Electrical Machines.
